

Bohlmicke

Bohläse, Germany

Basin characteristics

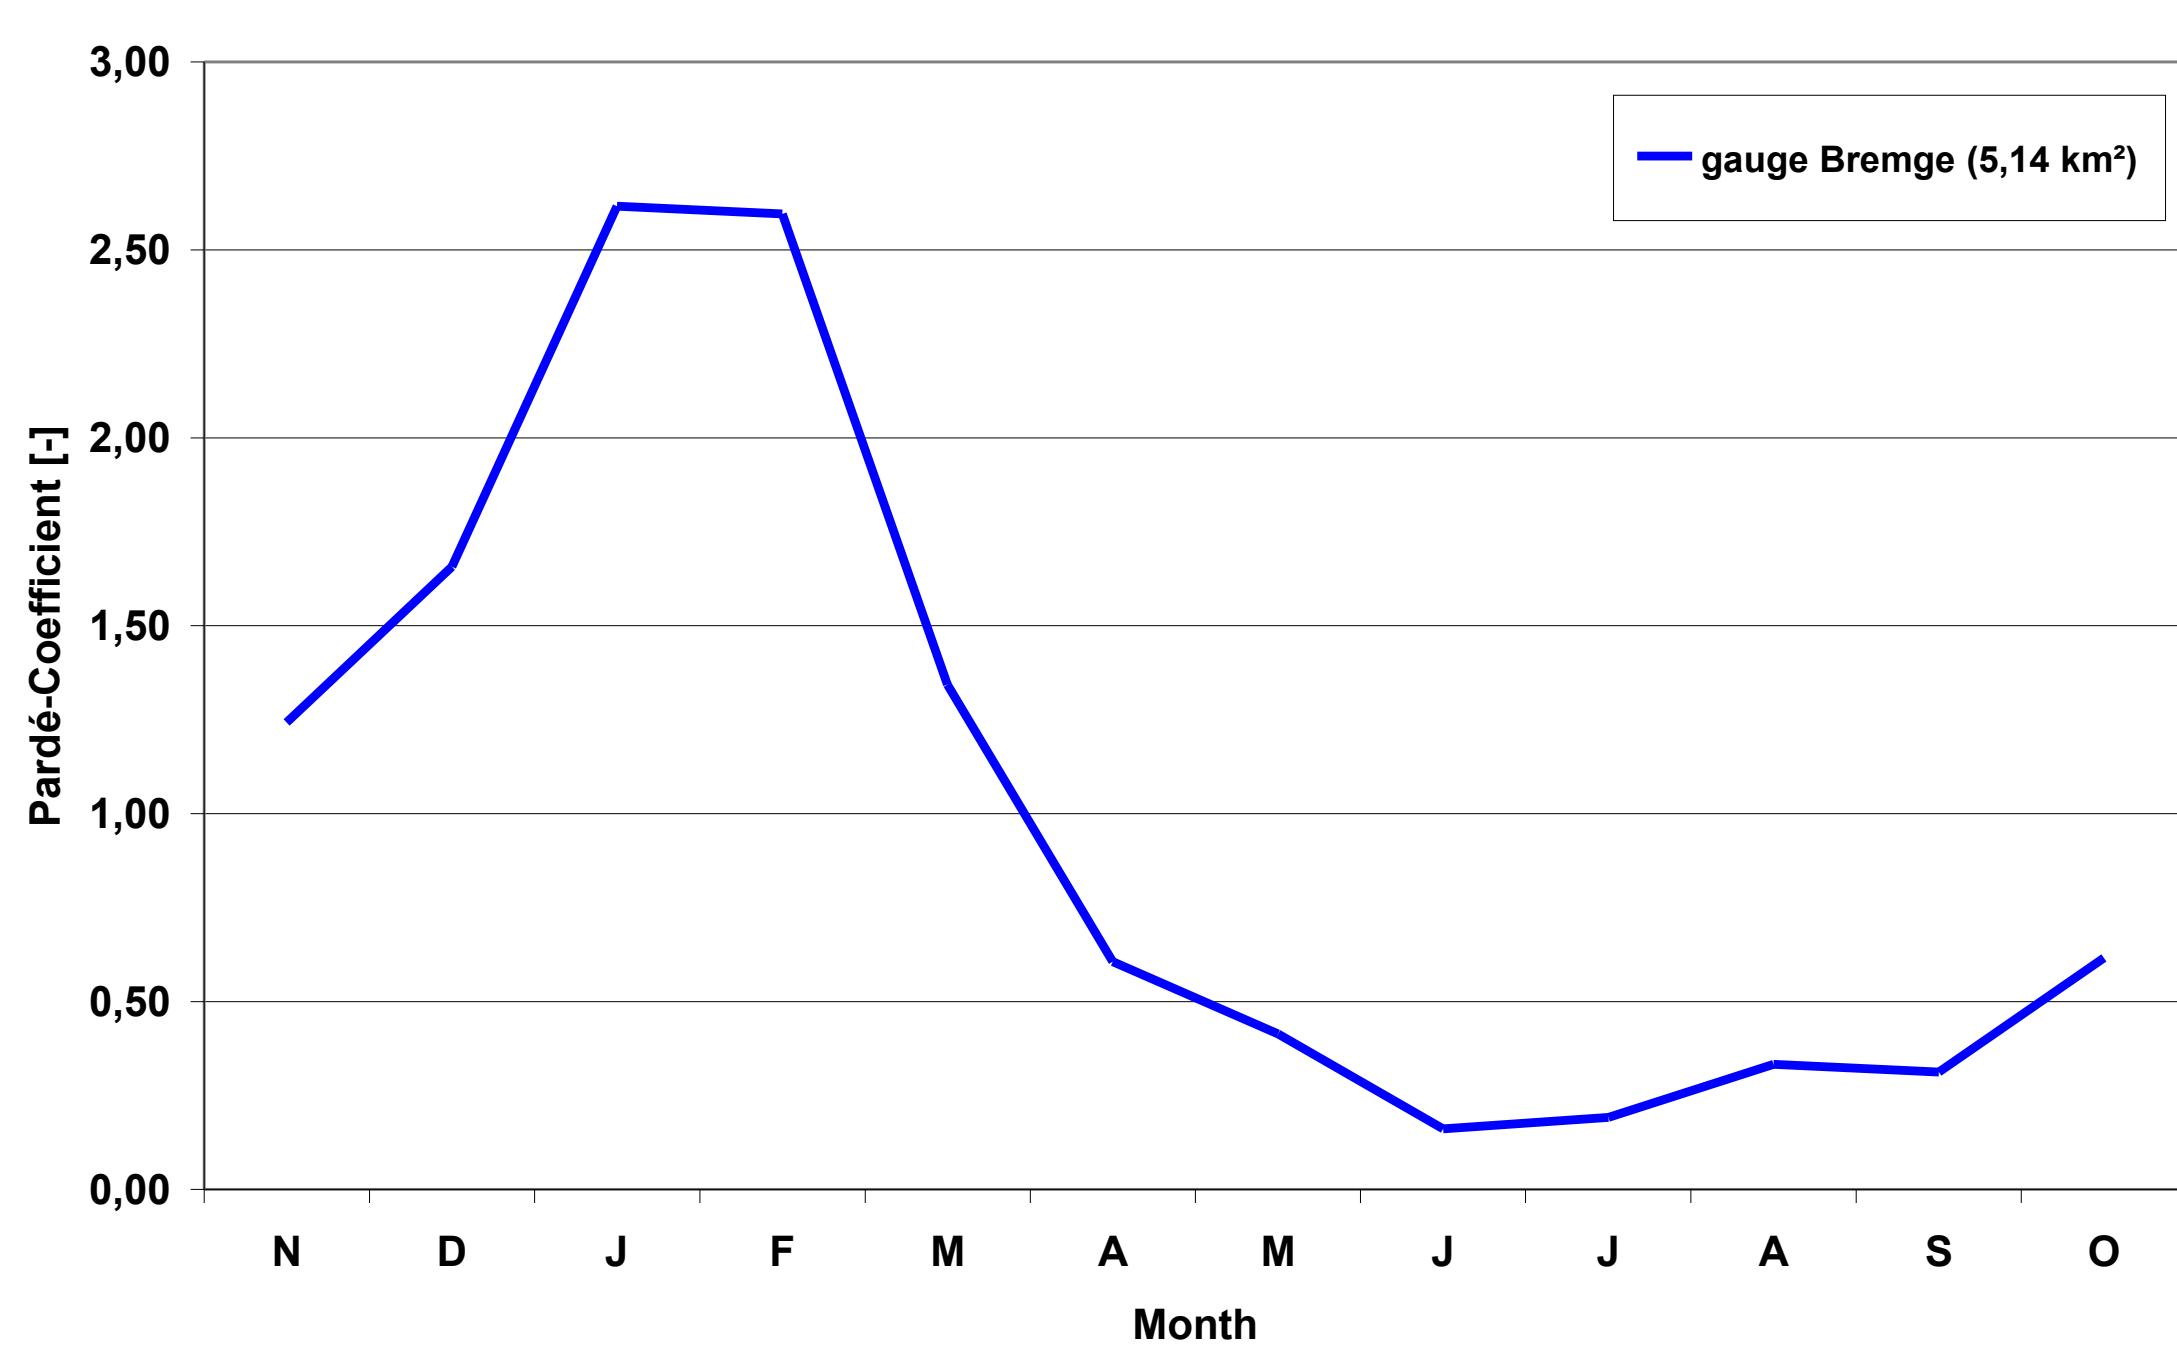

River Basin / River Basin (according EU-WFD)	Rhine
Operation (from... to...)	2000 to 2007
Gauge coordinates / Gauge datum:	N 51° 04.755, E 7° 53.570
Catchment area:	0,7 km ²
Elevation range:	382 to 425 m a.s.l.
Basin type:	low mountain range
(alpine, mountainous, lowland)	
Climatic parameters:	P: 1250 mm/a; T: Ø 8°C
(mean precipitation, temperature and others)	
Land use:	forest
Soils:	Cambisol, Leptosol
Geology:	grey clay shale
Hydrogeology:	unconfined aquifer
(Type of aquifers, hydraulic conductivity)	
Characteristic water discharges:	$Q_{\min} : 0,006 \text{ m}^3/\text{s}$; $Q_{\max} : 3,16 \text{ m}^3/\text{s}$; $Q_{\text{mean}} : 0,078 \text{ m}^3/\text{s}$

Map of the research basin

- soil hydrological measurement stations
 - 1) footslope I
 - 2) upperslope
 - 3) footslope II
- throughfall
 - 4) spruce forest (20-30 years)
 - 5) spruce forest (75-85 years)
 - 6) beech forest
- precipitation
- gauge Bohlmicke
- catchment „Bohläse“
- channel „Bohlmicke“

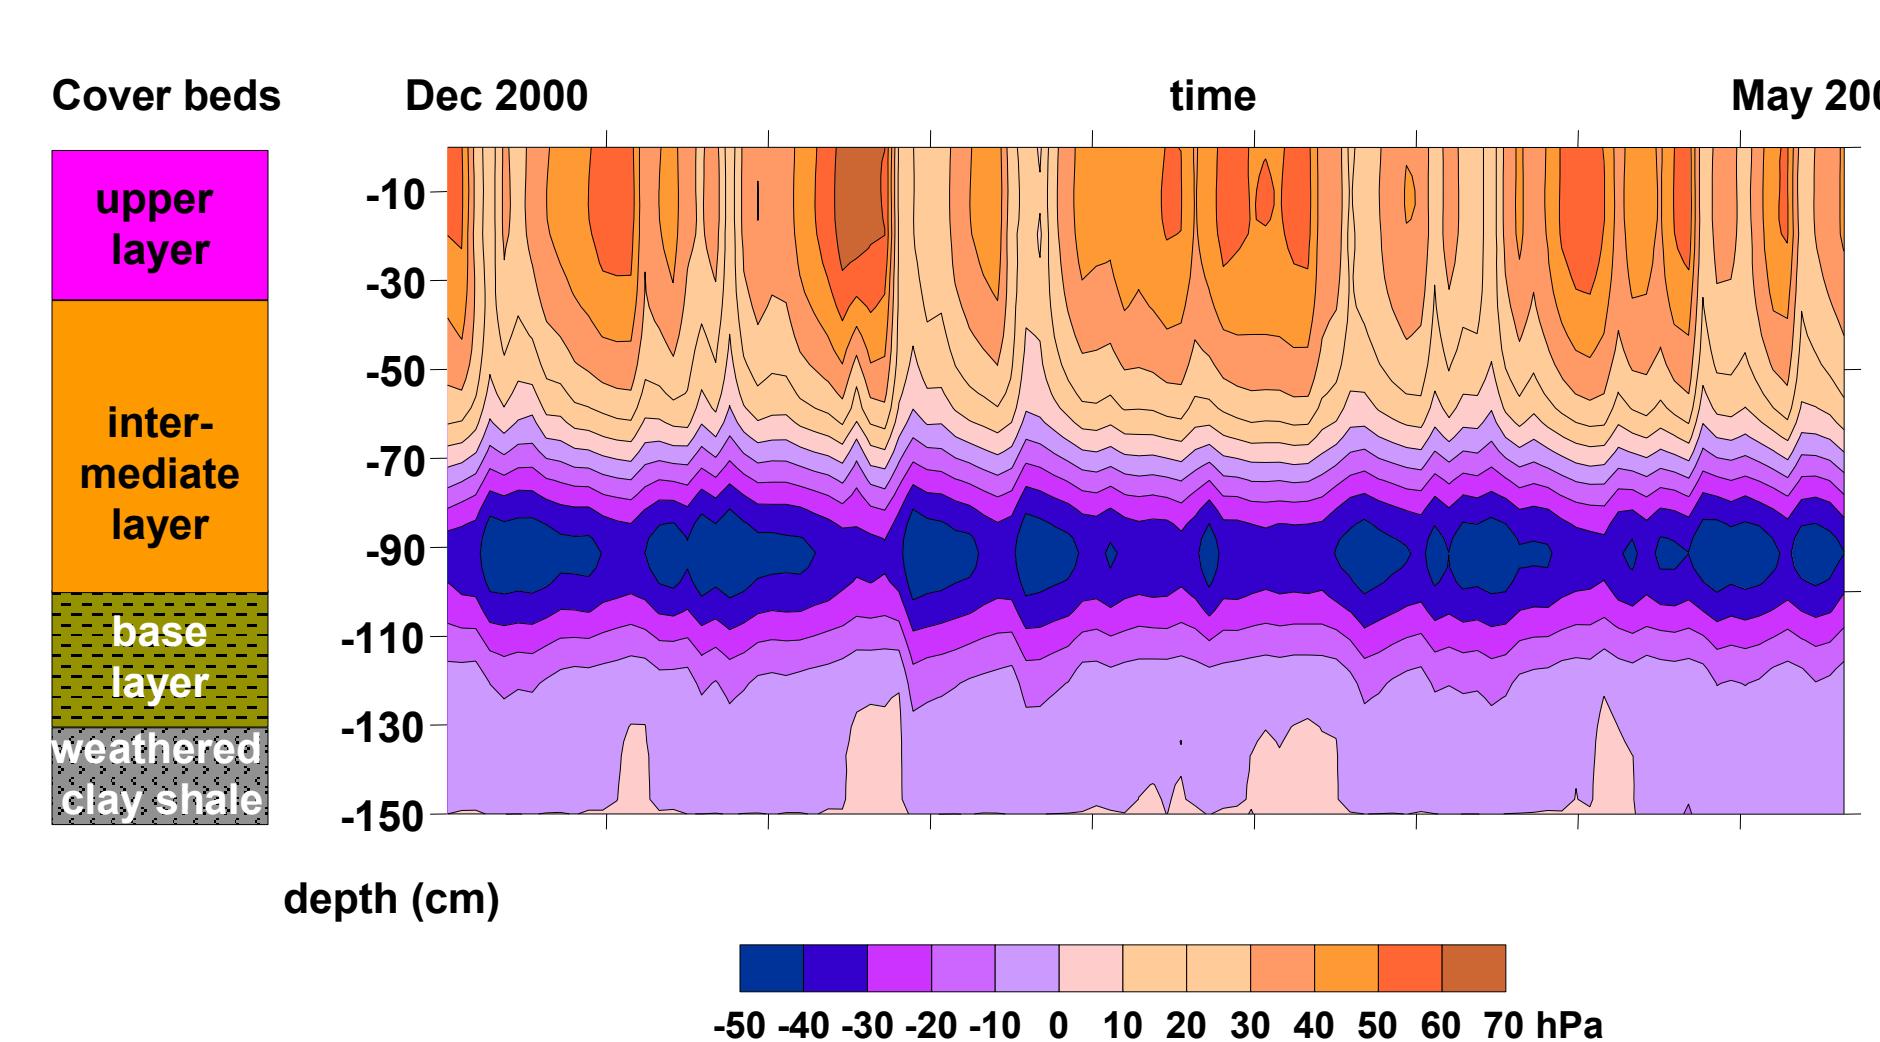

Mean hydrograph / Pardé flow regime

Pardé flow regime for gauge Bremge (2001-2003).
Catchment "Bohläse" is part of catchment "Bremge".

Special basin characteristics (hydrogeology, lakes, reservoirs etc.)

1. Catchment bears typical periglacial cover beds which are characteristic for low mountain ranges in middle europe.

3. Good opportunity to analyse the influence of the soil structure on the vertical and lateral soil water fluxes and on the runoff processes.

Instrumentation and data

Measured hydrological parameters	Measuring period	Temporal resolution	Number of stations
precipitation	2000 - 2007	weekly	1
throughfall	2000 - 2007	10 min weekly	2
discharge	2001 - 2007	10 min	1
soil water potential	2000 - 2007	10 min	3

Applied models

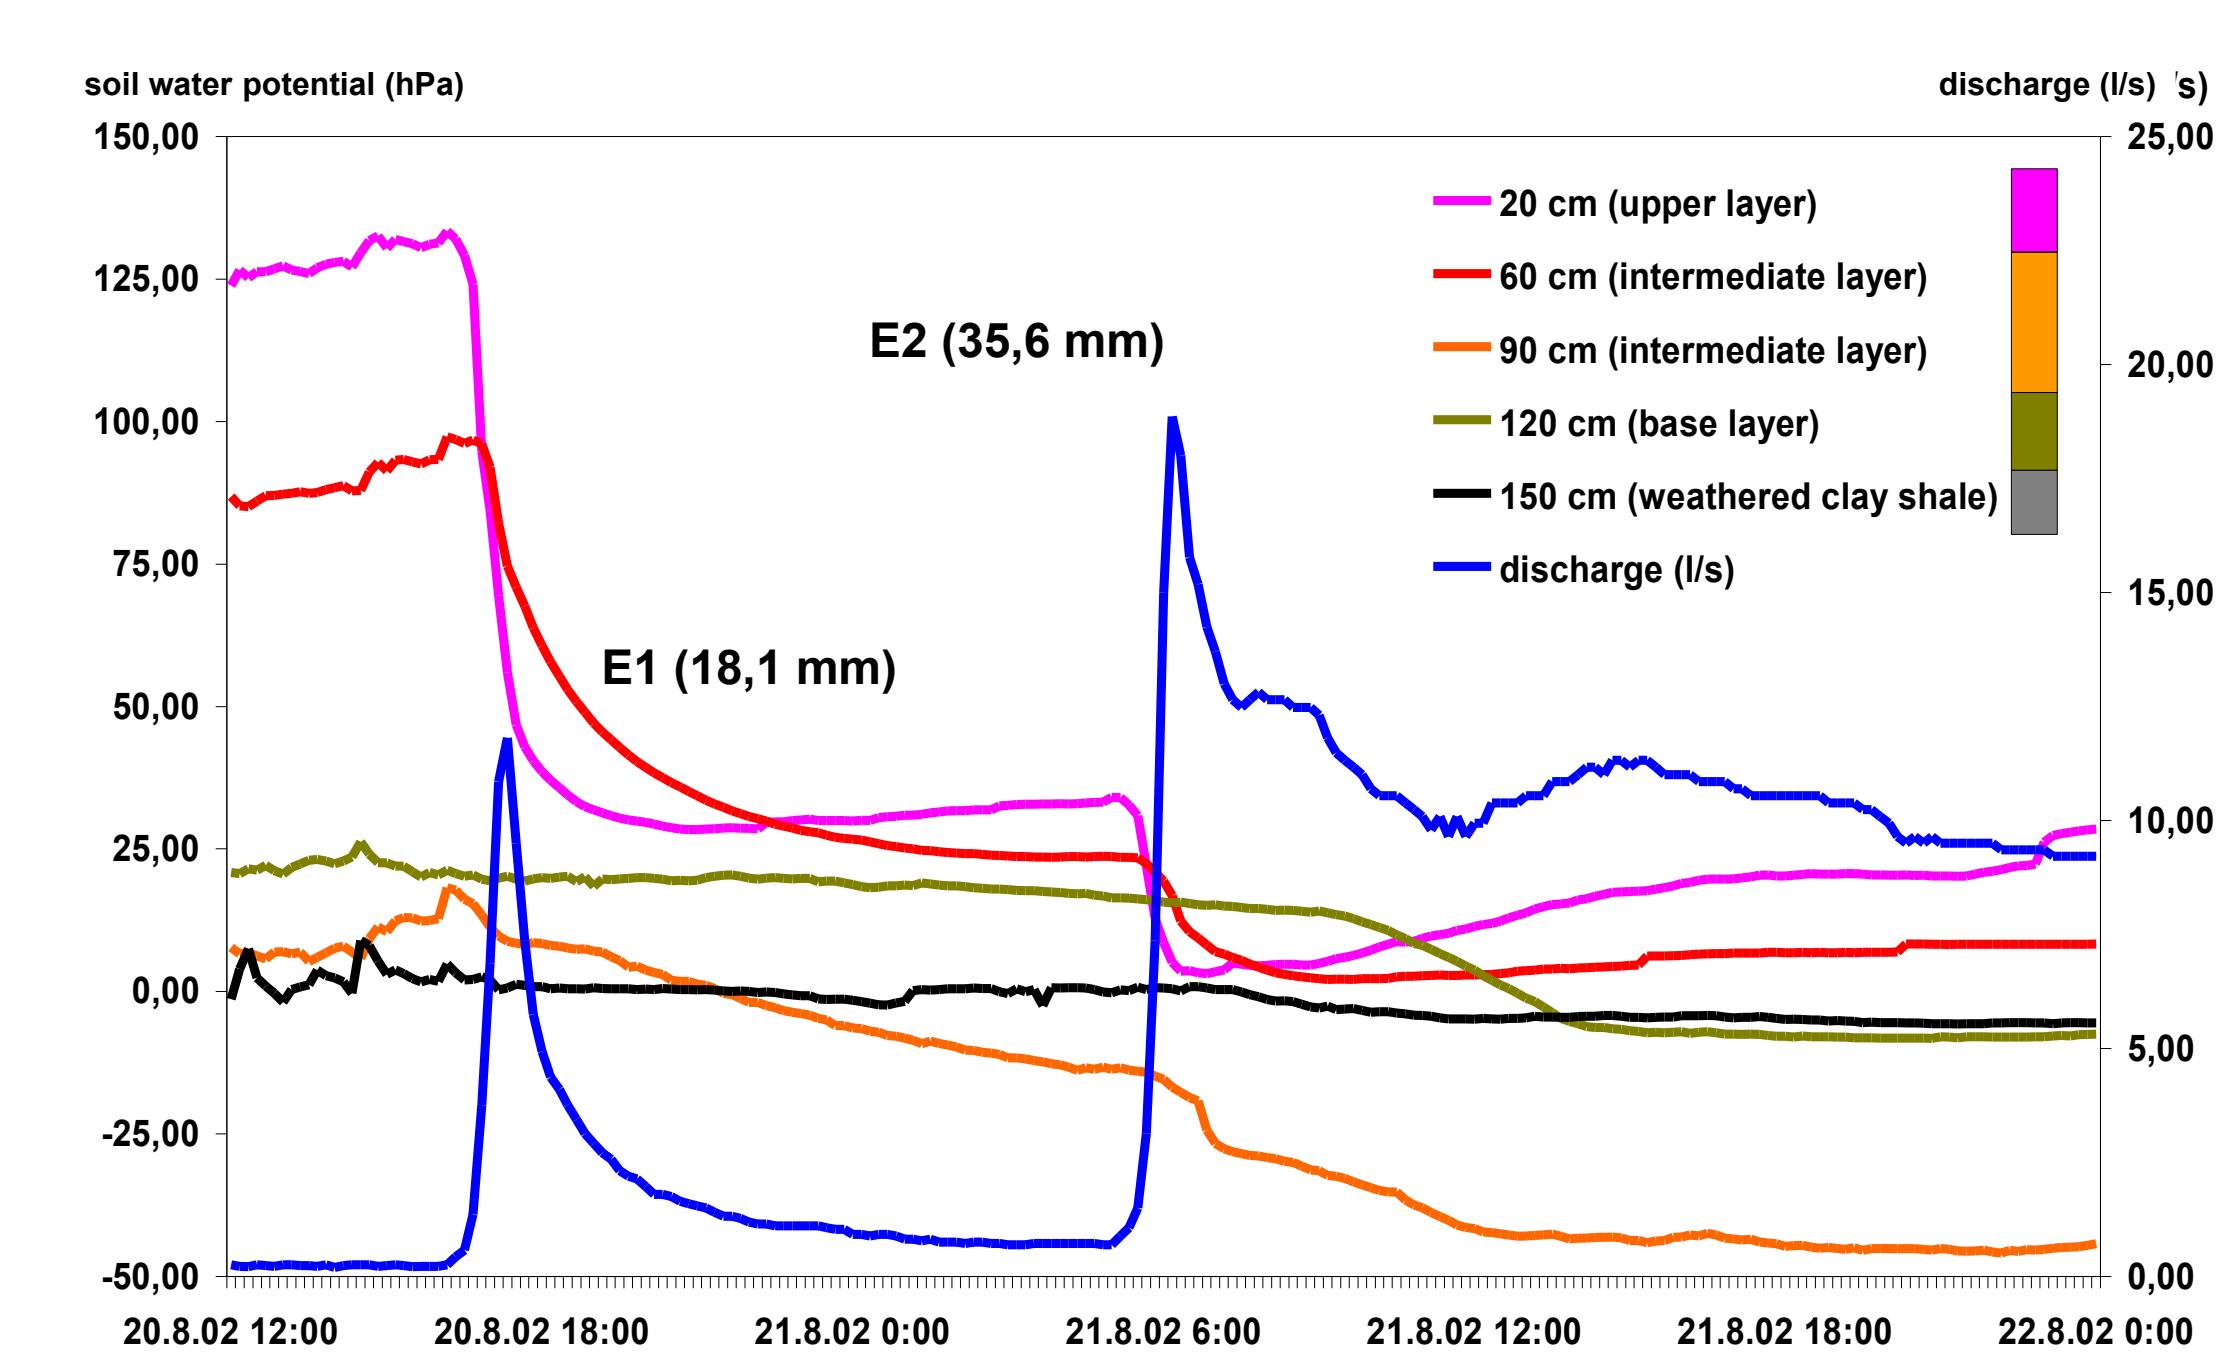

1. Any runoff model wasn't applied yet.

Main scientific results

Based on studies at different scales, runoff processes in the catchment "Bohläse" (Sauerland, Germany) were analysed during several rainfall-runoff-events. Using hydrological tracers and hydrometric methods, the influence of periglacial cover beds was determined for runoff at the catchment scale and for soil water flux at the point scale.

The process studies show that the influence of the base layer depends on the current water content. If the water content in the base layer is low, vertical water movement is impeded. On the other hand, if the water content is high, the base layer becomes a preferential flow path for interflow. Due to the spatial variability of the soil physical properties, the base layer functions as a preferential flow path for interflow only if the bulk density is low.

The results confirm the importance of periglacial cover beds for runoff processes in low mountain regions and represent an experimental basis for hydrological regionalisation depending on the spatial distribution of periglacial cover beds.
